Harmonic Analysis for a 6-pulse Rectifier

Sudeep Pyakuryal and Mohammad Matin
Department of Electrical and Computer Engineering University of Denver

Abstract: When sinusoidal voltage is converted into dc voltage in medium-voltage high-power applications, the switching devices used in the rectifier circuit inject harmonic component to the utility grid. The harmonic component causes various problems in the power system. IEEE std 519-1992 limits the amount of harmonics that is acceptable in the power system so that the undesirable effects of harmonic distortion are minimized.

Among various harmonic distortion mitigation techniques, the pulse multiplication technique is investigated in this paper. A 6-pulse rectifier is modeled in Alternative Transients Program (ATP). Voltage and Current waveforms are obtained and the amount of harmonic distortion is calculated. 6-pulse rectifier is a building block for higher order rectifier like 12-pulse, 18-pulse, 24-pulse rectifiers. Results suggest that the total harmonic distortion, THD, produced by an ideal 6-pulse rectifier is higher than the IEEE limit and therefore higher order pulse rectifier must be used to control the THD.

Keywords: AC to DC converter, Rectifier, THD, Thyristor, ATP

I. INTRODUCTION

Medium-voltage high-power drives are widely use in the industry. They are used in the petrochemical industry for pipeline pumps, in the cement industry for fans, in water pumping station for pumps, in transportation industry for traction applications, mills in the metal industry for steel rolling and in many other industries for various applications [1]-[8].

These drives are made up of power electronic components like power diodes, power IGBT, power thyristor etc. When these devices are turned on and off at certain frequency, these devices produce non-sinusoidal components called harmonics. These devices act as non-linear load to the utility [9].

IEEE standard 519-1992 requires that the amount of harmonic distortion produced by these drives should be under specified value. Criteria dictate that any individual harmonics should not be more than 3% and total harmonic distortion (THD) should not be more than 5% [10].

Presence of harmonics in power system can give rise to a variety of problems including equipment overheating, reduced power factor, deteriorating performance of electrical equipment, the incorrect operation of protective relays, interference with communication devices, and in some cases, circuit resonance to cause electric apparatus dielectric failure and other type of severe damage [11].

In order to meet the harmonic requirement set by IEEE standard 519-1992, major high-power drive manufactures around the world are increasingly using multi-pulse rectifier in their drive at front end converter. The rectifiers can be configured as 12-, 18-, and 24-pulse rectifiers powered by a transformer with a number of secondary windings. Each secondary winding feeds a 6-pulse rectifier. To achieve 12-pulse rectifier two 6-pulse rectifiers are used in parallel. Likewise, for 18-pulse, three 6-pulse rectifiers, and for 24-pulse, four 6-pulse rectifiers are connected in parallel [12]-[15].

The main feature of the multi-pulse rectifier is its ability to reduce the line harmonic distortion. This is achieved by the phase-shifting transformer through which some of the lower order harmonic currents generated by the six-pulse rectifiers are cancelled. In general, higher the number of rectifier pulses, the lower the line current distortion [12]-[15].

Multi pulse rectifier eliminates the need of using any LC filter or power factor compensators which leads to the elimination of possible LC resonance. The use of phase shifting transformer provides an effective means to block common-mode voltages generated by the rectifier which would otherwise appear on electric motor terminals leading to premature failure of winding insulation [16].

The multi-pulse rectifier can be built using diodes or thyristors as switching device. In case of diodes, dc output voltage cannot be controlled. On the other hand, thyristor provides the ability to control the dc output voltage. Fig 1 shows a general block diagram of medium-voltage drive [17].
II. IDEAL SIX-PULSE RECTIFIER

Fig 2 shows a simplified circuit diagram of a six-pulse thyristor rectifier. The inductance $L_s$ is the total inductance including the line inductance, transformer reactance, and line reactor between the utility and the rectifier. For the ideal rectifier $L_s$ is assumed to be zero. On the dc side a choke $L_d$ is used to make the dc current ripple free [18]. The RC snubber circuits for thyristor are not shown in Fig 2 but are considered in the computer model created in alternative transients program (ATP) [19].

**Figure 1.** General block diagram of the MV drive

**Figure 2.** Simplified circuit diagram of a six-pulse thyristor rectifier

Fig 3 shows typical waveforms of the rectifier, where $v_a$, $v_b$, and $v_c$ are the phase voltages of the utility supply, P1 thru P6 are the gate firing pulses for thyristors T1 thru T6 respectively and $\alpha$ is the firing angle of the thyristors.

During interval I, thyristors T1 and T6 are conduct assuming T6 was conducting prior to turn on of T1. The positive dc voltage is $v_p$ with respect to ground is $v_a$ and the negative bus voltage $v_n$ i.e. equal to $v_b$. The dc output voltage can be found from $v_d=v_p-v_n$. The line currents can be given as $i_a=I_d$, $i_b=I_d$ and $i_c=0$.

During interval II, thyristor T6 is turned off after T2 turns on and the dc current $I_d$ is commuted from T6 to T2. Thus T1 and T2 are conducting. The positive dc voltage $v_p$ is still the same i.e. $v_p=v_a$ but the negative bus voltage $v_n$ is equal to $v_c$. The dc output voltage can be found from $v_d=v_p-v_n=v_ac$. The line currents can be given as $i_a=I_d$, $i_b=0$, and $i_c=-I_d$.

Following the same procedure all the voltage and current waveforms in other interval can be obtained. It should be noted that the number of thyristor and gate is also the sequence of their firing.

The average dc output voltage can be given as [17]

$$V_d = 1.35 \frac{V_{LL} \cos \alpha}{\pi}$$  \hspace{1cm} (1)

The equation (1) depicts that the rectifier dc output voltage $V_d$ is positive when the $\alpha$ is less than $\pi/2$ and becomes negative for an $\alpha$ greater than $\pi/2$. However, the dc current $I_d$ is always positive irrespective of the polarity of the dc output voltage. The technique to control the dc output voltage by firing angle, $\alpha$, is called phase-control technique [20].

When the rectifier produces positive dc voltage, the power is delivered from utility to the load. With a negative dc voltage, the rectifier operates as an inverter and the power is fed from the load back to utility. This often takes place during rapid deceleration when the kinetic energy of the rotor and its mechanical load is converted to the electric energy by the converter working in inverter mode and are used for dynamic braking.
Harmonic Analysis for a 6-pulse Rectifier

The line current $i_a$ in Fig 3 can be expressed in a Fourier series as [17]

$$i_a = \frac{2\sqrt{3}}{\pi} I_d \left\{ \sin(\omega t - \phi) - \frac{1}{5} \sin(5\omega t - \phi) + \frac{1}{7} \sin(7\omega t - \phi) + \frac{1}{11} \sin(11\omega t - \phi) + \frac{1}{13} \sin(13\omega t - \phi) - \frac{1}{17} \sin(17\omega t - \phi) - \frac{1}{19} \sin(19\omega t - \phi) + \ldots \right\}$$

where $\phi$ is the phase angle between the supply voltage $v_a$ and the fundamental frequency line current $i_{a1}$.

The rms value of $i_a$ can be given as [17]

$$I_a = \sqrt{\frac{2}{3}} I_d = 0.816 I_d$$

From which the total harmonic distortion, THD, for the line current $i_a$ is [17]

$$\text{THD} = \frac{\sqrt{I_{a2}^2 - I_{a1}^2}}{0.78 I_d} = \frac{\sqrt{(0.816 I_d)^2 - (0.78 I_d)^2}}{0.78 I_d} = 0.311$$

where $I_{a1}$ is the rms value of $i_{a1}$, i.e. THD = 31.1%

III. CONCLUSION AND FUTURE WORK

The waveform of line currents $i_w$, $i_n$, and $i_c$ are not sinusoidal as shown in Fig 3. If these waveforms were perfectly sinusoidal, the total harmonic distortion, THD, would be zero. From equation (4) it can be seen that the THD of an ideal six-pulse thyristor rectifier is 31.1%. This value is significantly higher than the IEEE limit of 5%.

In low-voltage application, THD can also be mitigated using shunt reactor but in a medium-voltage application, using shunt reactor to control the THD is not cost effective, therefore pulse multiplication method is widely used. However, reactance due to cable inductance and transformer inductance will always be there in medium-voltage application and the THD will be mitigated to some extent. But to achieve the THD value under IEEE limit, pulse multiplication must be used.

In future, a practical circuit with cable inductance and transformer inductance will be considered for a 12-pulse and 18-pulse rectifier. To achieve a 12-pulse rectifier, two 6-pulse rectifiers will be connected in
parallel and to achieve an 18-pulse rectifier, three 6-pulse rectifiers will be connected in parallel. Resultant THD for both the cases will be calculated and waveforms for line currents will be obtained. If neither of these rectifiers produces less than 5% THD, a 24-pulse rectifier should be investigated.
