Abstract: - In the internet world, there is a need for strong cryptographic techniques for data transmission and storing confidential information. To do this, an approach has been made by using the mathematical proof of the existence of a consistent formation of the Euler totient function to generate a key. Then the principles of number theory functions have been proposed in the encryption/decryption process. Thus, this structure is simple and powerful to use; in generating a key, computation of encryption/decryption process and key transmission.

Keywords: - Cryptography, Euler Totient function, Number Theory, Testing tools, Modified RSA algorithm.

Date of Submission: 16-10-2018 Date of acceptance: 31-10-2018

I. INTRODUCTION

Technology is used in every field of science where people are more dependent on computer technology to exchange confidential information to others in a secure way. So a day-to-day use of cryptography [4] is increasing tremendously in all our life. Therefore, Cryptography is a modern encryption/decryption technology; consist of different mathematical formulas or algorithms that have been designed to secure the network communications and data authentication. Cryptography can be classified as Symmetric key algorithm and Asymmetric key algorithm. Symmetric-key algorithms [9] are also known as single- key, or private-key encryption that uses a Private (shared secret) key to execute encryption /decryption process. Some popular symmetric algorithms include DES [1], TDES [10], Blow fish [14], IDEA [5], AES [1], Two fish [2] and RC6 [11, 12]. Asymmetric key algorithms [3] also known as public key encryption where encryption and decryption are mathematically performed using different keys; one key act as public key and the other one as private key. Some popular asymmetric algorithms includes PGP [7], Diffie-Hellman keys [8], SSH [14] and SSL [16].

In the network communication, messaging of data is done by texting through components like phone, web, or mobile communication over the world. This data is potentially visible and vulnerable to eavesdroppers anywhere along its internet path or within the network. So the information at any moment can be modified by the intruder. For this reason, this paper is concern with the progress of securing the message mathematically by using cryptographic technique to protect the confidential data from unauthorized access and authenticated by the user.

This paper comprises into three sections namely, section 2 proposed the encryption and decryption process by using mathematical techniques like euler totient function and modular function. Section 3 explains the key generation, encryption/decryption process and key transmission to the authenticated users which has been implemented with an example and section 4 shows its security aspects and conclude with section 5.

II. PROPOSED SYSTEM

Data security refers to protect confidential information from unauthorized access of data. So cryptography plays an important role, where it has been attacked by few methods like brute force, dictionary attacks, side-channel attacks and targeted cipher attacks etc., To overcome these attacks, in the proposed method, the key is generated by using Euler totient function. This key is then xor'ed with the message for encryption and decryption process which is shown in fig.1. Though this proposed method looks simple, the complexity is depends on key generation process. Thus the encryption/decryption process is represented as,

III. **IMPLEMENTATION**

The proposed method is explained with an example given below,

KEY GENERATION PROCESS

The key has been generated with the help of Eular totient function where,

 ϕ (n) where n = $p_1^{\alpha_1}$, $p_2^{\alpha_2}$, ..., $p_k^{\alpha_k}$ $\phi(n) = n \left(1 - \frac{1}{p^1}\right) \left(1 - \frac{1}{p^2}\right) \dots \dots \left(1 - \frac{1}{p^k}\right)$ (Or) $\varphi(n) = n \prod_{p|n} \left(1 - \frac{1}{p}\right)$ (For both prime and non-prime numbers) Example: Let consider a word "IAMGO" as a key and is converted into its ascii value,

Ι	А	М	G	0
73	65	77	71	79

This ascii value is then applied to the euler totient function to generate the key as,

$$\begin{split} & \oint (n) = 73 \\ & \oint (73) = 73 \left(1 - \frac{1}{73} \right) = 72. \\ & \oint (n) = 65 \\ & \oint (65) = 65 \left(1 - \frac{1}{5} \right) \left(1 - \frac{1}{13} \right) = 48 \end{split}$$

Finally, the calculated key for "IAMGO" is 72, 48, 60, 70, 78 = H0<FN

ENCRYPTION

To do the encryption,

 $((\mathbf{P}_i \bigoplus \mathbf{K}_i) + \mathbf{K}_i) \mod 256 = Ciphertext$ Where \mathbf{P}_i is plain text and \mathbf{K}_i is the key generated from euler totient function. Let take a plain text and is converted into its binary value and then apply modular and XOR function along with

the generated key for encryption process as,

Ι	А	М	G	0	Ι	N	G	Н	0
01001001	01000001	01001101	01000111	01001111	01001001	01001110	01000111	01001000	01001111
М	E								
01001101	01000101								

Key:

72	48	60	70	78
01001000	00110000	00111100	01000110	01001110

0100100000110000001111000100011001001110

Cipher text	0010010011010000110101010100011101001111

This encrypted message is send to the receiver. Upon receiving the cipher text, the decryption process is done as,

DECRYPTION

The cipher text is decrypted by using inverse modular function as,

$(((C_i - K_i) \text{ mod } 256) \bigoplus K_i) = Plaintext$

Cipherte	0010010011010000110101010100011101001111
xt	
Key	0100100000110000001111000100011001001110010010000
Plaintext	0100100101000001010011010100011101001111

Original Plaintext:

KEY TRANSMISSION

To do encryption/decryption, the generated key must be transmitted to the authenticated users by using modified RSA Algorithm. The RSA Algorithm was named after Ronald Rivest, Adi Shamir and Leonard Adelman in 1977[13]. This algorithm has been used widely in Internet communications by Netscape Navigator, BitCoin, SSH, PGP and Microsoft Explorer web browsing programs. For RSA key exchange, secret keys are exchanged securely online by encrypting the secret key with the intended recipient's public key. Only the intended recipient can decrypt the secret key because it requires the use of the recipient's private key. Therefore, a third party who intercepts the encrypted, shared secret key cannot decrypt and use it. Unfortunately RSA is not much secure to various attacks like man-in-middle attack, brute force attack because of its key size . So to ensure the key is secure, a modified RSA algorithm is proposed by increasing the value of key size to improve its complexity. Thus, the Modified RSA can be generated by the following steps:

- 1. Selecting 3 prime numbers such as p, q and r.
- 2. Compute the modulus N as $n = p \times q \times r$
- 3. Select an exponent value E in a manner it should be $1 \le E \le \phi(n)$, where ϕ is an Euler's function.
- 4. Calculate $\phi(n) = (p-1)(q-1)(r-1)$
- 5. Calculate the private exponent D from e, p, q and r.
- 6. Output (n, e) as the public key and (n, d) as the private key.

The encryption is done by,

$C = m^e \mod n$

Where m is the message which needs to transmit to the receiver and the output C is the resulting ciphertext. The decryption is done by

$\mathbf{M} = \mathbf{c}^{\mathbf{d}} \mod \mathbf{n}$

ILLUSTRATION

The generated key is 72, 48, 60, 70, 78 = H0 < FN is transmitted to the receiver by using modified RSA algorithm

Let consider P= 3, q= 5, r=7 where N = p*q*r, N= 105, and ϕ (n) = (p-1) (q-1) (r-1) = (2, 4, 6) = 48 E = 11 (public key)

ENCRYPTION

 $C = m^{e} \mod n$ $C = 72^{11} \mod 105 = 18$

DECRYPTION

M = c^d mod n **Finding decryption Key D** = $\frac{1+K\phi(n)}{e}$ = 35, (private key) D = 18³⁵ mod 105 = 72

The time complexity is, Result of Evaluation

IV. SECURITY ANALYSIS

The proposed method is tested by using cryptographic tools like wireshark and translator binary tools to check its security against vulnerability attacks as,

BY USING TRANSLATOR BINARY TOOLS

To check the cipher text is secure or not, a translator binary testing tool is used in fig 4. This tool helps to identify whether the cipher text can be decrypted easily or not and prove the proposed method is secure against binary attacks.

Fig 6: Capturing a data between sender to receiver

By using wireshark tools, it has been tested to check security leakage between sender and receiver and vice versa while selecting the IP Address which is shown in Fig.5. Fig. 6 helps to check whether any leakage is visible or not. So this shows our proposed method is secure against man-in-middle Attack. Finally the overall time complexity of our proposed method is $18T+18T_x+1T_o$ which is shown in fig.7 is more secure.

Fig.7: Proposed method of securing message: Time complexity

V. CONCLUSION

Security plays a vital role in the wide area of data exchange and so the development of cryptographic algorithms also helps to secure such information. Mathematically, number theory functions have been used in almost all encryption and decryption algorithms. So in this paper we perceive a mathematical approach like Euler totient function, modular arithmetic and xor function which plays an important role in providing security aspects of transmitting the messages. The proposed method, thus helps to secure from the crypto attacks, reduce computation time and ease to access the chosen cryptosystem.
