Abstract: This research paper has been making an effort to current study of P (Proportional), PI (Proportional Integral), and PID (Proportional Integral Derivative) controller for speed control of IM (Induction Motor). Generally, the principle of operating a 3-phase IM (Induction Motor) specifies that motor speed is directly linked to frequency of supply. This detail has made inverter fed IM (Induction Motor) having a very common configuration in majority of industrial applications. The VSI-fed IM (Induction Motor) drives are progressively applied in several recent industrial applications that need tremendous transient performance of drives. Improved performance of P, PI and PID controller is deliberate and compared.

Keywords: Proportional (P), Proportional-Integral (PI), and Proportional-Integral-Derivative (PID), VSI-Fed IM

I. INTRODUCTION

One and all recognize vigorous role played by electrical motors in improvement of industrial schemes. IM (Induction motors) are currently a standard for industrial electrical drives and great recitational capricious speed drive applications have a series of benefits. There are numerous ways for speed control of IMs (Induction motors) fed through VSIs using diverse modulation methods. Investigators, expert and researchers are unceasingly inventing novel methods and approaches that cover speed control necessities of drive. Progressive control methods for instance fuzzy, genetic algorithm, neuro-fuzzy, sliding mode control, etc. have as well been comprehensively used in motion control applications. Intrinsically forthright working characteristics, flexible rectal and efficacynigorated use of VSI-fed IM (Induction Motors) in numerous kinds of industrial drive application. Utmost multiuse production machines profit from modifiable speed control, meanwhile frequently their speeds need change to augment the machine procedure or adapt it to numerous tasks for enhanced product feature, production speed.

VSIs are used to control speed of 3-phase SCIM (Squirrel Cage IM) by varying frequency and potential and entail of input rectifier, DC-link and output converter. They are obtainable for low potential range and medium potential range. The fundamental action involved in modifiable speed control of IM (Induction Motors) in is to apply an adjustable potential magnitude, and adjustable frequency to motor in order to attain an adjustable speed operation. Both Current Source Inverter (CSI) and Voltage Source Inverter (VSI) are used in modifiable speed AC-drives.

II. FUNDAMENTALS OF CONVENTIONAL CONTROLLERS

P-I-D controllers use three basic manners kinds of modes: P (Proportional), I (Integral) and D (Derivative). Even though P (Proportional) and I (Integral) modes are as well used as single control modes a D (Derivative) mode is seldom used on its own in control schemes. Such amalgamations for instance PI
(Proportional-Integral) and PID ((Proportional-Integral-Derivative) controller are very regularly in practical schemes.

(A) **P (PROPORTIONAL) CONTROLLER**

A P (Proportional) controller scheme is a kind of linear feedback control scheme. The P (Proportional) controller scheme is more difficult than on-off control scheme similar to a bi-metallic domestic thermostat, but modest than a P-I-D control scheme used in somewhat like an automobile cruise control. Generally it can be said that P (Proportional) controller can’t stabilize upper order processes.

For 1st order processes, connotation procedures with one energystowage, a large intensification in gain can be tolerated.

P (Proportional) controller can stabilize only 1st order unstable procedure. Varying controller gain K can change closed-loop dynamics. A great controller gain will consequence in control scheme with:

a) Better reference following i.e. lesser steady state error.

b) Broader signal frequency band of closed-loop scheme and higher sensitivity w.r.t. measuring noise i.e. Faster dynamics

c) Lesser amplitude and phase margin

![Fig.2. Block Diagram of P(Proportional) Controller](image)

In P (Proportional) controller procedure, controller output is comparative to error signal, which is difference amid set point and procedure adjustable. In P (Proportional) controller actuating signal for control act in a control scheme is proportional to error signal. The error signal being difference amid reference input signal and feedback signal attained from output.

The actuating signal is relative to error signal consequently; scheme is so-called P (Proportional) controller scheme.

The error of signal assumed as follows:

\[ e(t) = K [r(t) - h(t)] \]

It is anticipated that control scheme be under-damped for perspective of quick reply. An under-damped control scheme displays exponentially crumbling in output time response all through transient period.

(B) **PI (PROPORTIONAL INTEGRAL) CONTROLLER**

At present-day, P-I (Proportional-Integral) controller is most broadly accepted in industrial application because of its simple structure, simple to design and low price. In spite of these benefits, the P-I (Proportional-Integral) controller fails when controlled entity is very much nonlinear and undefined. P-I (Proportional-Integral) controller will eradicate forced oscillations and steady-state error ensuing in action of on-off controller and P (Proportional) controller correspondingly. Though, introducing I (Integral) mode has a negative (-ive) effect on speed of response and whole stability of scheme. Consequently, P-I (Proportional-Integral) controller will not escalation speed of response. It can be anticipated since P-I (Proportional-Integral) controller doesn’t have means to foresee what will occur with error in nearby future. This problematic can be resolved by presenting D (Derivative) mode which has capability to foresee what will happen with error in nearby future and consequently to diminution a reaction time of controller. P-I (Proportional-Integral) controllers are very regularly used in industry, particularly when response speed is not amatter. A control deprived of D (Derivative) mode is used when:

1. Fast response of scheme is not essential.
2. Enormous disturbances and noise are present all through the operation of procedure.
3. There is mere energy storage in procedure (capacitive or inductive).
4. There are enormous transport delays in scheme.
Consequently, keep benefits of P-I (Proportional-Integral) controller. This indication to suggest a P-I (Proportional-Integral) controller shown in Figure This controller uses of P (Proportional) term even though I (Integral) term is kept, unaffected.

\[ u(t) = K_p \cdot e(t) + K_i \int e(t) \, dt \]

Fig.3. Block Diagram of P-I (Proportional-Integral) Controller

The controller output in this circumstance is

\[ u(t) = K_p \cdot e(t) + K_i \int e(t) \, dt \]

Fig.3. Block diagram P-I (Proportional-Integral) controller an integral error compensation system, output response be subject to in some way upon integral of actuating signal. This kind of compensation is presented by means of a controller which produces an output signal entailing of 2-terms, one proportional to actuating signal & other proportional to its integral. Such a controller is so-called PI controller or proportional plus integral controller.

(C) PID (PROPORTIONAL-INTEGRAL-DERIVATIVE) CONTROLLER

Numerous industrial controllers employ a P (Proportional), I (Integral) plus D (Differential) i.e. PID regulator making ready that can be tailored to enhance a specific control scheme. PID (Proportional-Integral-Derivative) controller is utmost generally used algorithm for controller design and it is utmost broadly used controller in industry. The controllers used in industry are either one PID controller or its enhanced version. The basic kinds of PID (Proportional-Integral-Derivative) controller are parallel, serial and mixed controller. The PID (Proportional-Integral-Derivative) controller algorithm exploited for is design velocity algorithm; it is furthermore so-called incremental algorithm. In industry, PID (Proportional-Integral-Derivative) controllers are used most common control approach to use in real applications.

PID (Proportional-Integral-Derivative) controller has all essential dynamics: fast reaction on variation of controller input (Derivative mode), rise in control signal to lead error towards zero (Integral mode) and appropriate act inside control error area to eradicate oscillations (Proportional mode). Derivative (D) mode mends stability of scheme and permits escalation in gain K and diminution in integral time constant T, which escalations speed of controller response. PID (Proportional-Integral-Derivative) controllers are used most regularly used controllers in process industry. The majority of control schemes in world are operated PID (Proportional-Integral-Derivative) controllers. It has been described that 98 percent of control loops in pulp industries and paper industries are controlled by single-input single-output (SISO) PI (Proportional-Integral) controllers and that in process control applications, more than 95 percent of controllers are of PID (Proportional-Integral-Derivative) kind controller. PID (Proportional-Integral-Derivative) controller associations benefit of P (Proportional), D (Derivative) and I (Integral) control action.

\[ u(t) = K_p \cdot e(t) + K_i \int e(t) \, dt + K_d \frac{d}{dt} e(t) \]

The control signal is proportional to error signal and \( K_p \) (Proportional gain). A P (Proportional) controller will have effect of decreasing rise time and will diminish, but never eradicate. If an integrator is added, control signal

A Review on Speed Control of VSI-FED Induction Motor by P, PI and PID Controller

is proportional to integral of error and Ki (Integral gain). I (Integral) control will have effect of diminished error, in standard, to zero value. The in standard must be added, since there are continually limits on correctness in any scheme. D (Derivative) control is used to antedate future conduct of error signal by means of remedial actions based on rate of change in error signal. The control signal is proportional to D (derivative) of error and K_d is derivative gain.

D (Derivative) control will have effect of growing stability of scheme, diminishing overreach, and refining the transient response. D (Derivative) control action can by no means be used alone since this control action is in effect only during transient eras. The PID (Proportional-Integral-Derivative) controller makes a control loop retort faster with fewer overshoot and greatest popular technique of control by excessive margin. The collective action has benefits of each of 3-individual control activities.

Table 1 and table 2 displays effects of factors and effects of varying control parameters correspondingly. As we can there see is a diminution in rise time, overshoot and settling time and there is no change in steady-state error PID (Proportional-Integral-Derivative) Controller is improved than P (Proportional) and PI (Proportional-Integral) controller.

III. RECITAL ASSESSMENT OF P, PI, AND PID CONTROLLERS

It is to be illustrious that, when gain is growing response speed is growing in case of P (Proportional) and PID (Proportional-Integral-Derivative) controller but in PI (Proportional-Integral) controller gain of response is diminishing. In PID (Proportional-Integral-Derivative) controller there is a minor diminution or no changes are revealed in numerous parameters which can see from table 1 and table 2. In future there is no-change in steady-state error so PID (Proportional-Integral-Derivative) controller is enhanced than P (Proportional) and PID (Proportional-Integral-Derivative) controller.

IV. CONCLUSION AND FUTURE POSSIBILITY

P (Proportional) controller can stabilize only 1st order unstable procedure. PI (Proportional-Integral) controller can be used to evade large turbulences and noise presents all through operation procedure. However PID (Proportional-Integral-Derivative) controller can be used when dealing with upper order capacitive procedures. The study of P (Proportional), PI (Proportional-Integral) and PID (Proportional-Integral-Derivative) Controller is carried-out, in which PID (Proportional-Integral-Derivative) controller gives decent response than a few other controller. Additional output response of VSI-Fed IM (Induction Motor) drive will be estimated by using dissimilar controller i.e.P (Proportional), PI (Proportional-Integral) and PID (Proportional-Integral-Derivative) controller. Based on dissimilar industrial application of IM (Induction Motor), unsuitable controller can be preferred.
